METHOD FOR LAMINATING OVERLAYS

TO VERIFY PRINTING PLATES

CROSS REFERENCE TO RELATED APPLICATIONS

This is a divisional of application Serial No. 09/878,463, filed June
5 11, 2001.

FIELD OF THE INVENTION

The present invention relates to preparing overlay's to verify
printing plates, using a lamination method that uses pressure or heat and pressure
to laminate media together.

10 **BACKGROUND OF THE INVENTION**

Pre-press proofing is a procedure that is used primarily by the
printing industry for creating representative images of printed material. In the
printing industry, pre-press proofs are used to check for color balance, control
parameters, and other important image quality requirements, without the cost and
15 time that is required to actually produce printing plates, set up a printing press,
and produce an example of an representative image, which results in higher costs
and loss of profits that would ultimately be passed on to the customer.

To create a pre-press proof, first, an original image is separated
into individual color separations or digital files. The original image is scanned or
20 separated into the three subtractive primaries and black. Typically, a color
scanner is used to create the color separations or digital files and in some instances
more than four color separations or digital files are used. Although there are
several ways used in the printing industry to create a pre-press proof from the
color separations or digital files, they are generally of three types. The first
25 method being a color overlay system that employs the representative image on a
separate base for each color, then the image is overlaid on each other to create a
pre-press proof. The second method uses a single integral sheet process in which
the separate colors for the representative image are transferred one at a time by
lamination onto a single base. The third is a digital method in which the
30 representative image is produced directly onto a receiver stock, from digital files.

The representative image to be laminated can be, but is not limited
to being created on a commercially available Kodak image processing apparatus,

depicted in commonly assigned U.S. Patent No. 5,268,708 which describes an image processing apparatus having half-tone color imaging capabilities. The above-mentioned image processing apparatus is arranged to form a representative image onto a sheet of thermal print media. In this process, dye from a sheet of
5 dye donor material is transferred to the thermal print media by applying a sufficient amount of thermal energy to the dye donor sheet material to form the intended image. The image processing apparatus is comprised generally of a material supply assembly consisting of a lathe bed scanning subsystem. The scanning subsystem includes: a lathe bed scanning frame, translation drive,
10 translation stage member, printhead, imaging drum, and media exit transports.

The operation of the image processing apparatus comprises: metering a length of the thermal print media (in roll form) from the material supply assembly. The thermal print media is then measured and cut into sheet form of the required length and transported to the imaging drum, registered,
15 wrapped around, and secured onto the imaging drum. Next, a length of dye donor material (in roll form) is also metered out of the material supply assembly, then measured and cut into sheet form of the required length. It is then transported to the imaging drum and wrapped around the imaging drum utilizing a load roller which is described in detail in commonly assigned U.S. Patent No. 5,268,708. By
20 wrapping, it is superposed in the desired registration with respect to the thermal print media (which has already been secured to the imaging drum).

After the dye donor sheet material is secured to the periphery of the imaging drum, the scanning subsystem or write engine provides the imaging function. This imaging function is accomplished by retaining the thermal print
25 media and the dye donor sheet material on the imaging drum while it is rotated past the printhead. The translation drive traverses the printhead and translation stage member axially along the axis of the imaging drum, in coordinated motion with the rotating imaging drum. These movements combine to produce the intended image on the thermal print media.

30 Once a representative image has been formed on the thermal print media, the dye donor sheet material is then removed from the imaging drum. This is accomplished without disturbing the thermal print media that is beneath it. The

dye donor sheet material is then transported out of the image processing apparatus by means of the material exit transport. Additional dye donor sheet materials are sequentially superimposed with the thermal print media on the imaging drum.

These materials are then imaged onto the thermal print media previously

5 mentioned until the representative image is completed and transferred onto the thermal print media. The completed representative image formed thereon is then unloaded from the imaging drum and transported by the receiver sheet material exit transport to an exit tray in the exterior of the image processing apparatus.

After a representative image has been formed on the thermal print
10 media as previously described, it is then transferred to a receiver stock such that the pre-press proof is representative of an image that would be printed on a printing press. A Kodak Laminator as described in U.S. Patent No. 5,478,434 can be used to bond or laminate the representative image as part of a pre-press color proofing system but this invention is not limited to the use of this device. U.S.
15 Patent No. 5,203,942 describes a Kodak Laminator that employs a lamination/de-lamination system as applied to a drum laminator, and U.S. Patent No. 6,463,981 describes a Kodak Laminator that employs endless belts incorporated into the lamination apparatus. For the purpose of this patent application the laminator described in U.S. Patent No. 6,463,981 will be used. It should be noted that the
20 present invention described in this disclosure is not limited to a Kodak Laminator or to the type of laminator reference above.

Generally laminating a pre-press proof is a two pass process. For the first step, a sheet of pre-laminate, which has a pre-laminate support layer and a thermal print layer, encapsulation or protective layer, is placed on top of a receiver
25 sheet, which is also called "receiver stock" in the industry. This construction of multiple layers is a lamination sandwich, which is fed into the laminator. Once the lamination sandwich exits the laminator the pre-laminate support layer is peeled away from the now pre-laminated receiver stock.

For the second pass, the imaged thermal print media with the
30 representative image formed thereon is placed on the pre-laminated receiver stock with representative image face down on the pre-laminated receiver stock and fed into the laminator. After the lamination sandwich has exited the laminator, the

thermal print support layer is peeled away, leaving the completed pre-press proof simulating an image produced on a printing press.

While the above-described lamination method works well for both laser thermal inkjet pre-press proofs, there exists a need for an overlay to verify the image on printing plates prior to being used on the printing press.

SUMMARY OF THE INVENTION

The present invention provides a method of forming an overlay having a surface energy charge for verifying an image on printing plates formed by creating an imaged receiver sheet having an image, a first thermal print layer, and a first support layer. An imageless receiver sheet is laminated having a second thermal print layer and a clear second support layer with the imaged receiver sheet thereby encapsulating the image. The first support layer is removed.

The invention also relates to a method for verifying an image on a printing plate comprising the steps of: an overlay forming the method consisting of: creating an imaged receiver sheet having an image, a first thermal print layer, and a support layer; laminating an imageless receiver sheet having a second thermal print layer and a second support layer, which is preferably clear with the imaged receiver sheet, thereby encapsulating the image between the first thermal print layer and the second thermal print layer; removing the first support layer; removing the second support layer; adhering an overlay to a printing plate having an image, using an electrostatic charge; and viewing the overlay against the image on the printing plate for image quality and content.

The invention also relates to a method for verifying the image on a printing plate comprising the steps of: forming an overlay by the method consisting of: creating an imaged receiver sheet having an image, a first thermal print layer, and a first support layer; laminating an imageless receiver sheet having a second thermal print layer and a second support layer with the imaged receiver sheet thereby encapsulating the image; removing the first support layer; and adhering an overlay to a printing plate having an image, using an electrostatic charge.

The invention, its objects and advantages, will become more apparent in the detailed description of the preferred embodiments presented below.

BRIEF DESCRIPTION OF THE DRAWINGS

5 Figure 1 is a perspective view showing a laminator known in the related art used with the present invention.

 Figure 2 is a schematic right side elevation of the laminator known in the related art of Figure 1.

 Figure 3 is a block diagram of the present invention showing an
10 embodiment of a method for forming an overlay to verify printing plate.

 Figure 4 is a block diagram of the present invention showing a second embodiment of a method for forming an overlay to verify printing plate.

DETAILED DESCRIPTION OF THE INVENTION

 The present description will be directed, in particular, to elements
15 forming part of, or cooperating more directly with, an apparatus in accordance with the present invention. It is to be understood that elements not specifically shown or described may take various forms well known to those skilled in the art. For the sake of discussion, but not limitation, the preferred embodiment of the present invention will be illustrated in relation to a laminating apparatus for
20 making pre-press proofs.

 Referring to the drawings wherein like reference numerals represent identical or corresponding parts throughout the several views. Referring to Figure 1, there is shown a perspective view of laminator 10 as described in U.S. Patent No. 6,463,981. The laminator has an: entrance table 20, exit table 30,
25 entrance slot 40, pressure lever 50, top cover 60, right side cover 70, left side cover 80, control panel 90, and lamination base 100.

 Figure 2 is a schematic right side elevation of the laminator of Figure 1 showing endless belts 110 with upper lamination roller 120 and lower lamination roller 130 which convey media to be laminated through the laminator
30 10. Media to be bonded or laminated pass between the endless belts 110. Upper lamination roller 120 and lower lamination roller 130 provide heat and pressure to laminate the desired media together. This configuration with upper lamination

roller 120 and lower lamination roller 130 is known in the art as a “straight-through” lamination. Although the illustrated embodiments show both the upper lamination roller 120 and lower lamination roller 130 as heated rollers, it also should be recognized and only upper lamination roller 120 or lower lamination
5 roller 130 may be heated. It is further recognized that both upper lamination roller 120 and lower lamination roller 130 do not have to be heated for cold lamination applications to work within the scope of this invention.

Figure 3 is a block diagram outlining a method for forming an overlay 310 to verify an image 210 on a printing plate 300. Comprising the steps
10 of: creating an imaged receiver sheet 140 comprising an image 210, a first thermal print layer 224, and a first support layer 150 having; a support base 230, an aluminized layer 240, and a release layer 250. Laminating the imaged receiver sheet 140 to an imageless receiver sheet 160 having a second thermal print layer 228, and a second support layer 170, which is preferably clear, thereby
15 encapsulating the image 210 between the first thermal print layer 224 and the second thermal print layer 228. Next, the first support layer 150 is removed, resulting in an overlay 310, to verify a printing plate 300.

Figure 4 is a block diagram outlining an overlay 310 for verifying a printing plate 300 having a surface energy charge, formed by the method
20 comprising the steps of: creating an imaged receiver sheet 140 having an image 210, a first thermal print layer 224, and a first support layer 150 having; a first support base 234, an aluminized layer 240, and a first release layer 254; laminating an imageless receiver sheet 160, having a second thermal print layer 228, and a second support layer 170, which is preferably clear, having; a second
25 support base 238, and a second release layer 258, with the imaged receiver sheet 140, thereby encapsulating the image 210; removing the first support layer 150, and removing the second support layer 170, forming an overlay 310, to verify a printing plate 300.

The invention also relates to a method for verifying an image 210
30 on a printing plate 300 comprising the steps of: adhering an overlay 310 to a printing plate 300 having an image 210, using an electrostatic charge; and viewing said overlay 310 against said image 210 on said printing plate 300 for image

quality and content; wherein said overlay 310 is formed by a method comprising the steps of: creating an imaged receiver sheet 140 comprising an image 210, a first thermal print layer 224, and a first support layer 150 having; a support base 230, an aluminized layer 240, and a release layer 250. Laminating the imaged receiver sheet 140 to an imageless receiver sheet 160 having a second thermal print layer 228, and a second support layer 170, which is preferably clear, thereby encapsulating the image 210 between the first thermal print layer 224 and the second thermal print layer 228. Next, the first support layer 150 is removed, resulting in an overlay 310, to verify a printing plate 300.

The invention also relates to a method for verifying an image 210 on a printing plate 300 comprising the steps of: adhering an overlay 310 to a printing plate 300 having an image 210, using an electrostatic charge; and viewing said overlay 310 against the image 210 on the printing plate 300 for image quality and content; wherein the overlay 310 is formed by a method comprising the steps of: creating an imaged receiver sheet 140 having an image 210, a first thermal print layer 224, and a first support layer 150 having; a first support base 234, an aluminized layer 240, and a first release layer 254; laminating an imageless receiver sheet 160, having a second thermal print layer 228, and a second support layer 170, which is preferably clear, having; a second support base 238, and a second release layer 258, with the image receiver sheet 140, thereby encapsulating the image 210; removing the first support layer 150, and removing the second support layer 170, forming an overlay 310, to verify a printing plate 300.

The thermal print layer 220, first thermal print layer 224, and second thermal print layer 228 of the above described methods for forming an overlay 310 preferably has a thickness ranging from 1 micron to 75 microns, and most preferably is a thickness ranging from 1 to 25 microns and are made of a Butvar material, but could be a polyacrylate material, or other materials known in the art.

The image 210 of the imaged receiver sheet 140 of the above described methods for forming an overlay 310 preferably has a resolution of between about 1400 and about 4000 dpi, and most preferred the image receiver sheet 140 has a resolution of between about 1800 and about 3000 dpi.

In alternative embodiments, the second support layer 170 is clear.

In one embodiment, the material for the thermal print layer 220, first thermal print layer 224, and second thermal print layer 228 encapsulating the image 210 is most preferably a Butvar having the same thickness on both sides.

5 In alternative embodiments, the encapsulating material of the thermal print layer 220, first thermal print layer 224, and second thermal print layer 228 is contemplated as a polyacrylate, Butvar, or other material well known in the art. Whether a polyacrylate, Butvar, or other material well known in the art, the thickness of the thermal print layer 220, first thermal print layer 224, and
10 second thermal print layer 228 can be identical or disparate to each other.

 In performing the methods described above, it is considered within the scope of the invention that the lamination temperatures ranges up to about 160° C and preferably, 130° C for dye-based and pigment-based images. Pressures for the methods described above are around 80 psi.

15 In embodiments of the invention described above, the image 210 can be generated by laser thermal, inkjet combinations thereof, or other methods well known in the art.

 In embodiments of the invention described above, the imaged receiver sheet 140 can have a monochrome image or multicolor image.

20 In alternative embodiments the first support layer 150 can comprise a support base 230, first support base 234, and second support base 238; an aluminized layer 240, first aluminized layer (not shown), and second aluminized layer (not shown); a release layer 250, first release layer 254, and second release layer 258 or combinations thereof.

25 The support base 230, first support base 234, and second support base 238 can be made of polyester, polyethylene, combinations of the two materials, or other materials well known in the art.

 The invention has been described in detail with particular reference to certain preferred embodiments thereof, but it will be understood that variations
30 and modifications can be effected within the scope of the invention.
